DATA BASE FOR TEETH AND LIMB BONES OF MODERN HEMIONES

par

Vera EISENMANN*, Marjan MASHKOUR**

INTRODUCTION

The members of the genus *Equus* may be reasonably assigned to 6 groups : Horses, Hemiones, Asses, Mountain Zebras, Plains Zebras, and Grevy's Zebras (Groves and Willoughby 1981). We are concerned here with the group of Hemiones.

As their very name indicates, Hemiones are supposed to be « Half Asses ». Craniological characters (Eisenmann 1980) were found to agree with this statement : Hemiones appear intermediate between Horses and Asses, but closer to Asses than to Horses. When the purely morphological resemblances were checked by a tentative cladistic approach, Hemiones remained the sister group of Asses (Eisenmann 1979b). Chromosomal studies gave similar results (Ryder *et al.*, 1978) ; trees based on mitochondrial DNA cleavage maps failed to strongly discriminate the branching order of Asses and Hemiones (Matthew and Ryder 1986). Anyway, there seems to exist a consensus as to the close relationship between Asses and Hemiones (Oakenfull and Clegg 1998, fig. 5).

Groves and Mazak (1967) and Groves (1986) split Hemiones into two specific groups : 1. Kiangs, and 2. other Hemiones. Each group is subdivided in subspecies. There are three subspecies of *E. kiang* (*E. k. kiang* in Western Tibet, *E. k. polyodon* in Southern Tibet, and *E. k. holdereri* in Eastern Tibet), and six subspecies of *E. hemionus* (the Hemippe of Syria - *E. h. hemippus* -, the Onager of Persia - *E. h. onager* -, the Kulan of Turkmenistan - *E. h. kulan* -, the Khur of India - *E. khur* -, and the two Dziggetais of Mongolia - *E. h. hemionus* - of Kazakhstan, northern Mongolia, Transbaikalia, and - *E. h. luteus* - of southern Mongolia and adjacent Kansu). Thus, there are nine geographical taxa. Some confusion exists about the Hemiones found near Kichik Ulan Ussu (near Barkul, Sinkiang) which are referred to *E. h. luteus* by Groves and Mazak (1967), but to *E. h. hemionus* by Groves (1986).

In his detailed monograph, Bannikov (1981) insists on the conspecificity of Kiangs and other Hemiones. He quotes G.E. Grumm-Grjimailo and Przewalski, who were not able to say to what « species » (*E.*

* Laboratoire de Paléontologie, UMR 8569 and ESA 8045, 8 rue Buffon, 75005 Paris- France. E-mail : vera@mnhn.fr

** Laboratoire d'Anatomie Comparée, ESA 8045 and EP 1730, 55 rue Buffon, 75005 Paris- France. E-mail : mashkour@mnhn.fr

kiang or *E. hemionus*) belonged the animals they have seen North-West of Nan-Shan. Moreover, he distinguishes only eight geographical forms, which are not quite the same as those distinguished by the precedent authors : *E. h. hemionus* (Mongolia), *E. h. finschi* (Kazakstan, very poorly known), *E. h. onager* (Turkmenia, Uzbekistan, Eastern Transcaucasia, Iran (excluding the South-East), Afghanistan), *E. h. khur* (Western Pakistan and Western India, South-East of Iran), *E. h. hemippus* (Syria), *E. h. kiang* (Western Tibet), *E. h. holdereri* (Central and North-Eastern Tibet, Altyn-Tag, Kuku-Nor surroundings, Western Nan-Shan), and *E. h. polyodon* (Sikkim, the nearby Tibet, North-East of Nepal). Bannikov observes that *E. h. hemionus* are closer to *E. h. kiang* than to *E. h. onager*.

A recent detailed and beautiful monograph (G. and H. Denzau, 1999) reviews extant African Asses and Asian Hemiones and provides numerous photographs, illustrations, and maps. This work is based not only on bibliographical data, but also on personal studies in the wild, in particular of Onagers, Dziggetais, Kiangs, and Khurs. The authors distinguish nine forms : *E. hemionus hemionus* (the Dziggetai, including *E. hemionus luteus* as a synonym), the extinct *E. hemionus castaneus* (the Kazakhian Kulan, including *E. hemionus finschi*), *E. hemionus kulan*, *E. hemionus onager*, *E. hemionus khur*, the extinct *E. hemionus hemippus*, *E. kiang kiang* (Western Kiang), *E. kiang holdereri* (Eastern Kiang) and *E. kiang polyodon* (Southern Kiang). In their opinion, there is no written proof for Bannikov's assertion of an unclear boundary between Kiang and Dziggetai (G. and H. Denzau, 1999, p. 22). Although the horizontal gap between the two distributions is not very big, the different elevation and the extreme dry desert belt in between are possibly effective barriers between the two populations. It is interesting, however, to note that G. and H. Denzau observe that Kiangs are closer to Mongolian Dziggetais than to Indian Khurs (1999, p. 47).

The exact relationships between all these forms are still debatable. The access to the animals is difficult, some forms have completely disappeared, many are endangered and parked in reserves or zoos (G. and H. Denzau, 1999). The material collected in the wild is scanty, and the corresponding information is not altogether reliable and frequently imprecise. When osteological and biomolecular approaches are used in parallel as in the case of the collaboration (presently in progress) initiated by the European Endangered Species Program (Eisenmann and Shah 1996 ; Schreiber *et al.*, 1996), they provide not quite concordant results, possibly because they are not based on equivalent samples. Sticking to pure craniology, principal components analyses of the 160 available skulls (personal data) show that : -Eastern Kiangs ($n = 9$ specimens) are larger than Western ($n = 5$) and Southern ($n = 3$) ; - there is no difference between *E. hemionus* from Northern Mongolia ($n = 3$) and Southern Mongolia ($n = 23$) ; but, obviously, these samples are much too small. It is more interesting to remark that skulls of Kiangs ($n = 35$) do not differ much from skulls of Dziggetais ($n = 29$) except by a slightly larger size, and that the only skulls to segregate well from all the other belong to Khurs ($n = 27$).

Hemione taxa appear in our tables (Tables 1-28) and in figure 3 with codes based on an approximate biogeographic distribution : HS (Syria), HP (Persia), HT (Turkmenistan), HI (India), HM (Mongolia) (*i.e.* the initial of Hemione followed by the initial of the country) and K for Kiangs. Our schematic map of the geographical « historic » distribution of all Hemiones (fig. 1) is mostly based on the data gathered, analysed, and commented by Matschie (1911), Solomatin (1973), Bannikov (1981), and Denzau (1999) and localised on the Atlas of Stielers (1908). It may be of interest, because it points precisely the type localities, and the easternmost, northernmost and southernmost localities of the distribution during the past two centuries. It does not give precise westernmost points because it is yet unclear whether the fossil European *Equus hyduntinus* was a kind of Hemione or an altogether different taxon (Eisenmann and Mashkour, 1999). Localities corresponding to our sample are indicated in figure 2.

ORGANIZATION OF DATA

Each individual is defined by a code (see above) followed by a number. On the next two lines appear the codes for the collection and the catalogue numbers of these collections. On the next lines appear indications on the origin, the sex, and the age.

For instance, HS 1 is an Hemippe, bearing the number 1867.12.3.1 in the collections of the British Museum, it comes from Syria, it is a female, middle aged.

COLLECTIONS AND THEIR CODES

France : Muséum national d'Histoire naturelle, Paris, Laboratoire d'Anatomie Comparée (AC), Laboratoire des Mammifères et Oiseaux (MA). Muséum d'Histoire naturelle, Lyon (LY).

Germany : Zoologisches Museum der Humboldt Universität, Berlin (BL). Museum Koenig, Bonn (BO). Naturmuseum und Forschungsinstitut Senckenberg, Frankfurt (FR). Zoologisches Institut und zoologisches Museum, Hamburg (HA). Institut für Haustierkunde, Kiel (KI). Zoologische Sammlung des Bayerischen Staates, Munich (MU).

Great Britain : British Museum (Natural History), London.

India : material collected by Dr Nita Shah, studied at Dehra Dun (Dehra Dun).

Iran : Faculty of Sciences of the University of Tehran (FSUT).

Netherlands : Zoologisch Museum, Amsterdam (AM). Rijksmuseum van Natuurlijke Historie, Leiden (LD).

Russia : Zoological Museum of the Moscow University (MS). Zoological Institute, St Petersburg (LG).

Switzerland : Naturhistorisches Museum, Basel (BA). Muséum d'Histoire naturelle, Genève (GE).

Tchek Republic : National Museum (Natural History), Praha (PR).

United States of America : Field Museum of Natural History, Chicago (CH). Museum of Comparative Zoology, Harvard University, Cambridge (MCZ). American Museum of Natural History, New York (NY). Smithsonian Institution, Washington (WA). Peabody Museum, Yale (YA).

ORIGIN, SEX, AGE

When possible, a more or less precise locality of collection is given, either by its name (Badkhyz reserve) or by its geographical coordinates (36°N 55°E). A nickname (Ortiz) or studbook number of a Zoo animal, when known, is specified. Sex is noted when it is known. Ages are either given in years (when they are known or when they can be estimated in subadults), not specified for unknown middle-aged specimens, or specified as « Old » (according to the state of the dentition). Juvenile, subadult and very worn dentitions were not measured.

COMMENTS ON THE DATA AND SAMPLES

A cursorial look at the data tables suffices to show their shortcomings. Data may be lacking not only because some teeth or bones were missing, or damaged, or pathological, but also because the measurements were not taken ; it is the case of some proximal limb bones (for example in Hamburg collections) for which, due to lack of time, only the maximal lengths were measured. Also, during the thirty

years of data collecting, several new measurements were added ; the corresponding blanks could not always be filled.

However, the major problem concerns the samples themselves. In a general way, collections include more isolated skulls than complete skeletons, therefore data on limb bones are poor.

They are dramatically few for Khurs and Hemippes. In Khurs, they can possibly be augmented because the Khurs are extant. But in the case of the extinct Hemippes, our data base may only be augmented by the addition of the specimens preserved in Vienna (Austria) which we have not yet seen.

Onagers and Kulans exemplify other problems. Nearly all Kulans come from the Badkhyz reserve in Turkmenistan : they have lived in the wild, the skeletons are few, and the restricted geographic origin may possibly cause an artificial homogenization (it is the same for the Khurs which nearly all come from the Kutch reserve). On the other hand, nearly all Onagers are zoo-bred specimens : the skeletons are relatively numerous, but both skulls and limb bones suffer from age and zoo conditions ; the variation may appear larger than it was in a normal population. Denzau (1999, p. 108) remarks that it has never been clarified whether the Onagers of Southwest Iran differ from those further Northeast, and if so, the larger variation of Onager samples might also be due to this reason.

For Dziggetais and Kiangs, yet other difficulties arise. Apart from the difficulty of tracing their exact origin, the samples are not balanced : we have no skeletons at all of « northern Mongolia-Transbaikalia » Dziggetais or of « southern » Kiangs.

COMMENTS ON THE MEASUREMENTS

Measurements are always in millimetres (Plates 1-4)

TEETH

Teeth measurements are neither precise nor utterly reliable, in part because of individual variations mostly (but not only) due to wear. Various methods have been proposed to neutralize the effect of wear but neither is satisfactory. In particular, measurements systematically taken at 1 or 2 cm from the roots do not describe the same stage of wear for all equids : in moderately hypsodont form, the crown may still function normally (with a more or less normal enamel pattern) while in animals with very high crowns no enamel at all is left at that level, and one may wonder whether the teeth could be of any use. In practice, we recommend the following ways to deal with the problem : not to take in account very worn specimens ; when possible, section and/or measure at mid-crown ; when teeth are included in maxilla or mandibles, the inevitable occlusal measurements should be « adapted ». For example, for upper cheek teeth, the relation between length of the protocone and occlusal size is better expressed not by the classic protocone index (protocone length versus occlusal length) but by relating the protocone length to the mean of occlusal length and breadth. This is possible, because there is a relatively good compensation between the two values during wear (young teeth tend to be long and narrow, worn teeth tend to be short and broad). This cannot be done for lower cheek teeth, because the compensation between length and breadth is not as simple, and because the length of the double knot and of the postflexid vary much more than the protocone length. In that case, we recommend even more caution in the choice of data : for lower cheek teeth, measurements may only be meaningful if they concern middle-worn specimens.

The system of measurements presented here has evolved since the previous proposals (Eisenmann 1979a, 1986 ; Eisenmann *et al.* 1988). Accordingly, we give another set of illustrations for each limb bone. Even though complete limb bones are rare in an archaeozoological context, total lengths are interesting to evaluate segment proportions. In relation to that point, we want to stress the importance of distinguishing anterior and posterior first phalanges : various equids have not the same ratios between these two bones. Actually, first phalanges are a good example of the fact that imprecise and arduous measurements may still be of value : supratuberosital and infratuberosital lengths are difficult to measure, but their relation is discriminant.

CONCLUSIONS

Figure 3 is a ratio diagram (Simpson, 1941) comparing the average maximal lengths of humerus (H), femur (F), radius (R), tibia (T) third metacarpal (MC), third metatarsal (MT), first anterior phalanx (PhI A), first posterior phalanx (PhI P), to the average maximal breadth of the third anterior phalanx (PhIII A 4) and to the average protocone lengths and occlusal sizes of upper P3P4 and M1M2. Note, that we use the average mean of occlusal length and breadth.

Figure 3 shows that the main differences between Hemiones are size-related. All variables belonging to Kiangs, Dziggetais, and Kulans are larger than the corresponding variables of Onagers – our reference zero line ; all the variables corresponding to the Hemippes are smaller ; Khurs are intermediate. Hemippes are so much smaller than the other subspecies that there would be room for another subspecies in between. It is interesting to note that the fossil (black square in fig. 2) *E. hemionus binagadensis* (Eisenmann and Mashkour, 1999) fills in this size gap (fig. 3 : BNG).

The relative size of different bones and teeth are not altogether identical for all Hemiones. Dziggetais exhibit relatively short proximal segments (Humerus, Femur, Radius, and Tibia) in comparison to distal (MC III, MT III, PhI A and P). They appear thus more « cursorial » than the other Hemiones.

The next obvious but perhaps not significant difference is in the third phalanges : they are relatively wide in Kiangs and Kulans, relatively narrow in Dziggetais, Khurs, and Hemippes (and in *E. hemionus binagadensis*). Relatively wide third phalanges may be an adaptation to soft ground (snow or sand) : snow and/or sand are indeed part of the environment for Kiangs (Groves, 1974, 91-92) and Kulans (Bannikov, 1981, 36, 41-42). But Bannikov (1981, 40) states that the biotopes are similar for Kulans and Dziggetais ; and G. and H. Denzau (1999, 45) illustrate a very impressive Dziggetai sand track. Accordingly, one would rather expect Dziggetais to have as wide third phalanges as Kiangs and Kulans. Our samples are, however, very small.

Figure 3 shows also that the average dimensions of the upper cheek teeth (occlusal size and protocone length) are closer than the average dimensions of the limb bones, with the exception of Hemippes.

Eventually, this data base may prove useful to compare not only different taxa inside the group of Hemiones, but also Hemiones in general to other equids, in particular to Horses, and true Asses.

Acknowledgements.

Our first thanks are for all curators and colleagues who gave us access to their osteological collections. Special thanks are due to Gertrud Denzau, Waltraut Zimmermann, and Arnd Schrieber for their help in collecting data and for fruitful discussions. Maps could not have been realised without the precious collaboration of Cecilia Rodriguez Loredo.

10. Condylar height
11. Lateral condylar height

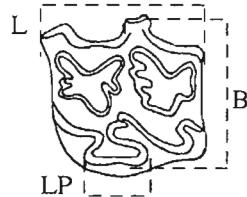

L. Length

B. Breadth

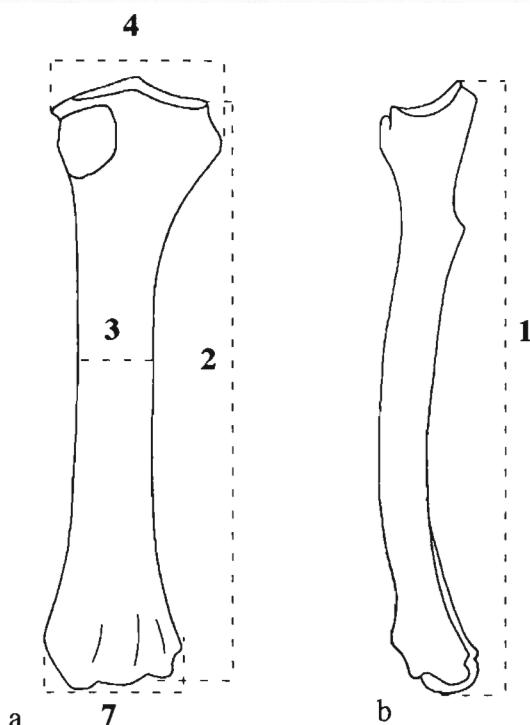

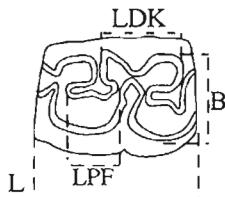

LP. Length of the protocone

LDK. Length of the double knot
LPF. Length of the postflexid

UPPER CHEEK TEETH

LOWER CHEEK TEETH

a- dorsal view

c- distal view

b- lateral view

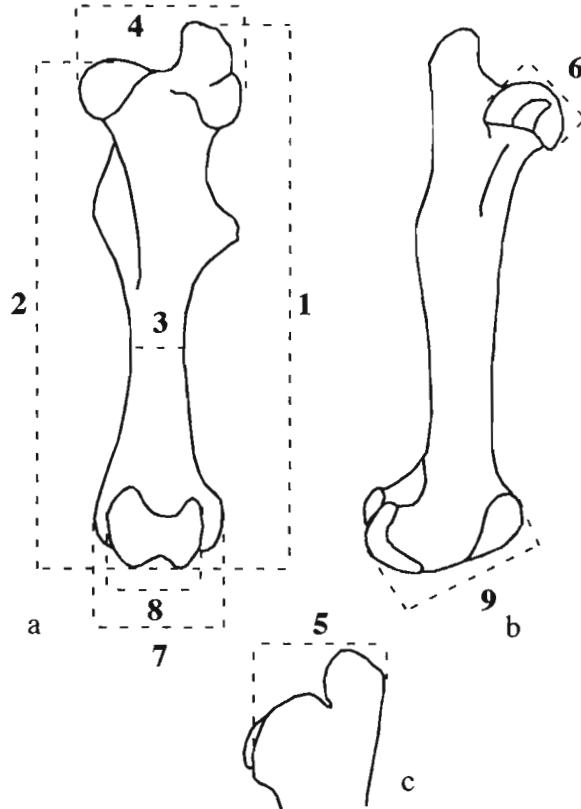

d- proximal view

RADIUS

1. Greatest length
2. Lateral length
3. Smallest breadth
4. Proximal breadth
5. Proximal articular breadth
6. Proximal articular depth
7. Distal breadth
8. Distal articular breadth
9. Greatest distal articular depth
10. Breadth of radial condyle
11. Breadth of ulnar condyle

Plate 1 - Lower and Upper Cheek Teeth, Humerus and Radius

FEMUR

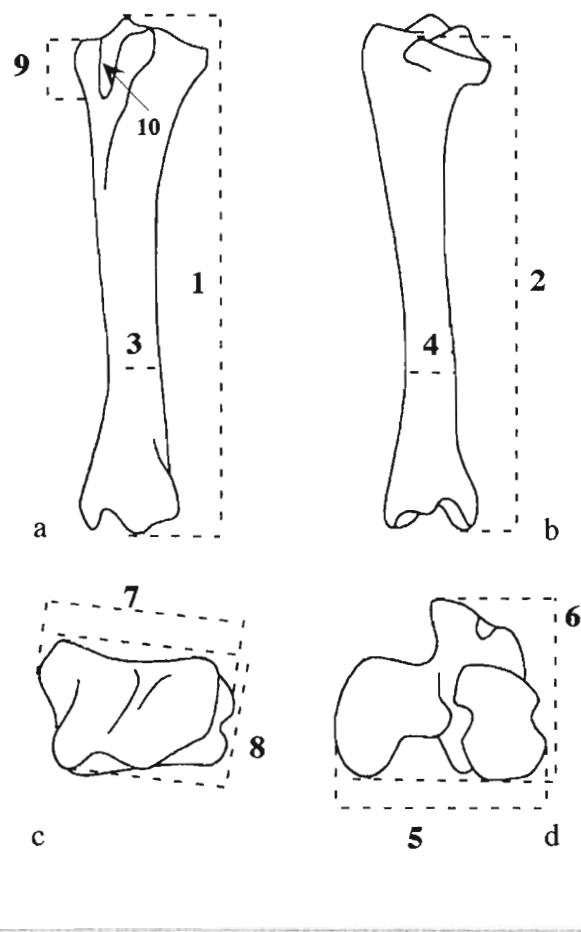

a- anterior view

b- medial view

c- proximal end, caudal view

TIBIA

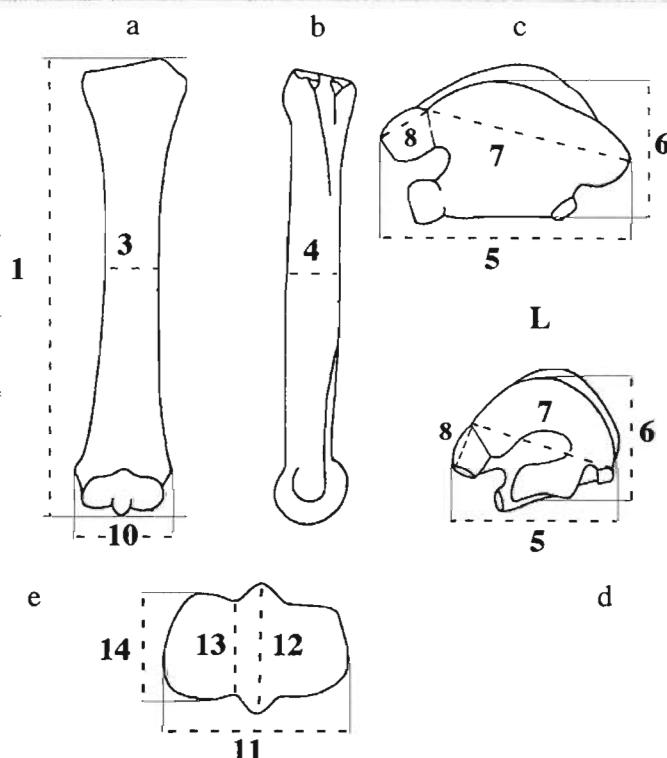

a- dorsal view

b- lateral view

c- distal view

d- proximal view

Plate 2 - Femur and Tibia

THIRD METAPODIALS

1. Greatest length
3. Breadth at midshaft
4. Depth at midshaft
5. Proximal breadth
6. Proximal articular depth
7. Diameter of articular facet for Os carpale and tarsale III
8. Diameter of articular facet for Os tarsale IV
10. Distal supra-articular breadth
11. Distal articular breadth
12. Depth of sagittal keel
13. Smallest depth of medial condyle
14. Greatest depth of medial condyle

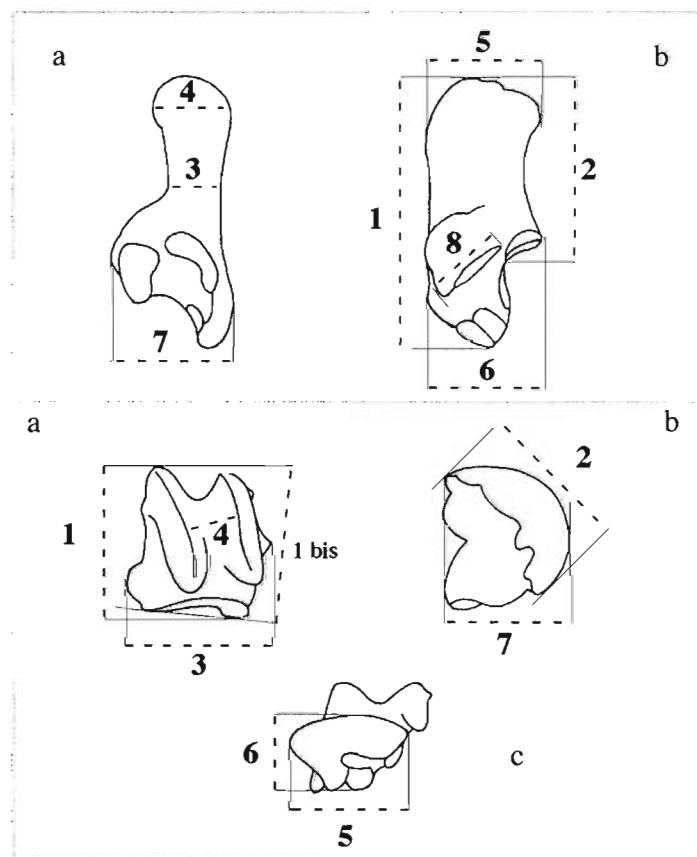

a- dorsal view

b- lateral view

c- metacarpal proximal view

d- metatarsal proximal view

e- distal view

CALCANEUM

1. Greatest length
2. Length of proximal part
3. Smallest breadth
4. Proximal breadth
5. Proximal depth
6. Distal depth
7. Greatest breadth
8. Diameter of articular facet

a- dorsal view

b- medial view

TALUS

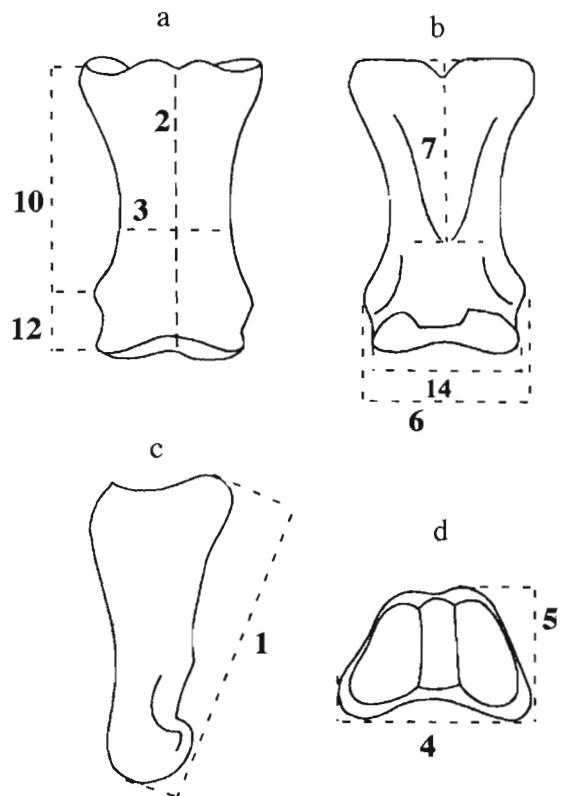

1. Greatest length, orthogonal
- 1bis. Greatest length, oblique
2. Medial length of the trochlea
3. Greatest breadth
4. Trochlear breadth
5. Distal articular breadth
6. Distal articular depth
7. Medial depth

a- dorsal view

b- medial view

c- distal view

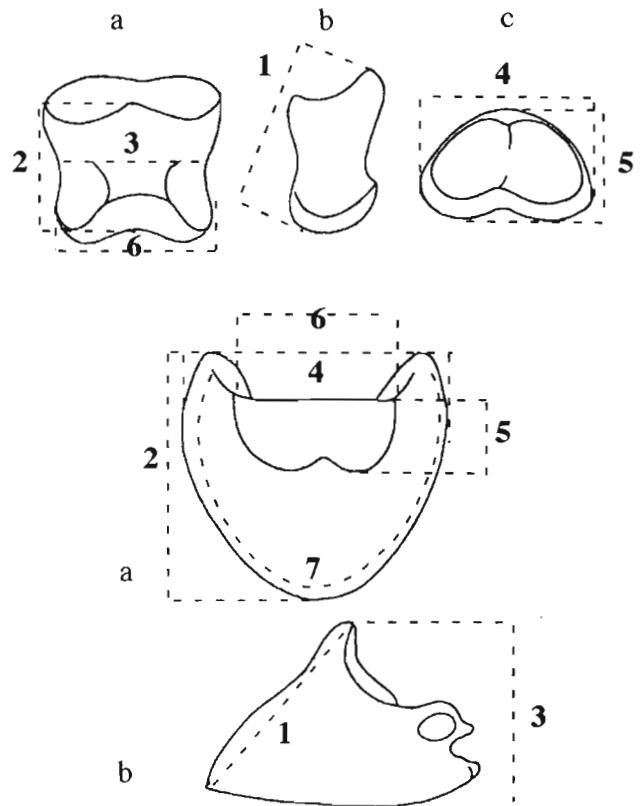

Plate 3 - Third Metapodials , Calcaneum and Talus

FIRST PHALANX

a- dorsal view
c- lateral view

b- plantar view
d- proximal view

SECOND PHALANGES

a- dorsal view b- lateral view c- proximal view

THIRD PHALANGES

a- dorsoproximal view
b- side view

PH I & II

1. Greatest length
2. Anterior length
3. Smallest breadth
4. Proximal breadth
5. Proximal depth
6. Distal supra-articular breadth
7. Greatest length of trigonum phalangis
10. Medial supra-tuberosital length
12. Medial infra-tuberosital length
14. Distal articular breadth

Codes 1 to 5 identical for first and second phalanges

PH II

6. Distal articular breadth

PH III

1. Anterior length
2. Greatest anteroposterior diameter
3. Height
4. Greatest breadth
5. Articular anteroposterior diameter
6. Articular breadth
7. Distal circumference

Plate 4 - First, second and third Phalanges

Table 1- Upper and lower cheek teeth
